The **only PDF you'll ever need** to master

ICT DAILY BIAS

40+ PAGES

This content is for education, not investment recommendations

DISCLAIMER

This PDF is created for educational purposes only. The content inside is based on personal study, market observation, and experience using price action concepts. It is not financial advice, investment advice, or a recommendation to trade any specific market.

Financial markets involve substantial risk. Trading can result in partial or complete loss of capital. There is no guarantee of profits, and no strategy or concept can eliminate risk. Past market behavior does not guarantee future outcomes.

The concepts explained in this material are designed to help you understand market direction, structure, and decision-making processes. They are frameworks for learning not promises of performance. Your results will depend entirely on your discipline, emotional control, risk management, and execution.

You are solely responsible for your trading decisions. Always test any idea in a risk-free environment before committing real capital. Never trade with money you cannot afford to lose. By using this material, you accept full responsibility for your actions in the market and acknowledge that all trading decisions are made independently at your own risk.

UNDERSTANDING

Daily bias is simply your directional expectation for the market during one trading day. It is your structured opinion about whether price is more likely to move higher or lower.

It is not about predicting every candle or catching every move.
It is about starting your day with clarity instead of confusion.

When you trade without a bias, every small movement can influence your emotions and make you change direction constantly. Daily bias gives you a mental anchor. It helps you approach the market with a plan instead of reacting to every fluctuation.

The goal of daily bias is not to be perfect or right every time. The goal is to create a framework that guides your decisions. You are trying to understand the overall intention of the market for that day.

Are buyers likely to dominate?
Are sellers more in control?

Or is the market likely to remain balanced? By asking these questions before entering trades, you reduce impulsive decisions and increase patience. Daily bias builds discipline because it forces you to think before you act.

For beginners, daily bias should be viewed as a daily roadmap, not a prediction tool. It gives direction to your trading ideas and filters out unnecessary trades. Even if the market does not follow your expectation, the process of forming a bias strengthens your analytical thinking. Over time, this habit creates consistency in how you approach the market.

Daily bias is not about controlling price it is about controlling your mindset and aligning yourself with the most probable direction of the day.

MISS UNDERSTANDING

One of the biggest misunderstandings about daily bias is that traders think everyone should use it in the same way. This is where many ICT traders struggle. Sometimes their direction is correct, but price moves in their expected direction only after they get stopped out.

The problem is not always their analysis the problem is mismatch between their trading style and the timeframe they used to build their bias.

Before finding daily bias, you must first understand what type of trader you are.

Are you a scalper? A day trader? A swing trader? This is extremely important. Your holding time decides which timeframe deserves the most attention when forming bias.

If you are a scalper entering trades on the 1-minute chart and holding positions for 10 to 15 minutes, you are not trading the entire day's move. You are trading a small intraday expansion. In this case, focusing heavily on the Daily or 4H chart can create confusion. You may build a strong daily bias, but the market can move against that direction for hours before expanding. As a scalper, that temporary move can stop you out, even if your higher-timeframe idea is correct.

This does not mean higher timeframes are useless. You still need awareness of major levels. But your real structure and decision making should come from 1H, 15M, and 5M.

For scalpers, the 15-minute timeframe is often the most important because it shows intraday structure clearly while still being relevant to short holding periods. Your bias should align with the type of move you are actually trying to capture.

Now, if you are a day trader entering on the 5M or 15M chart and holding trades for several hours, daily bias becomes much more important. You are exposed to larger market expansions. In this case, the Daily and 4H charts help define the real direction of the day. Day traders need daily bias because they are participating in the broader intraday narrative, not just small session moves.

Finally, if you are a swing trader, the concept changes again. Swing traders hold positions for days or even weeks. In this case, focusing only on daily bias is not enough. You must shift your attention to higher timeframes like the Weekly. Your bias is no longer just “daily bias” it becomes weekly or even monthly bias, depending on your entry timeframe. The higher your holding time, the higher the timeframe that should guide your directional expectation.

This is where many traders make mistakes they mix these styles without realizing it. They enter like a scalper but build bias like a daytrader. Or they hold like a day trader but analyze like a scalper. That mismatch creates frustration.

BIAS FIRST

Before looking for entries, the market's direction must be clear.
Without a daily bias, every setup is random.

TOOLS

There is no single correct way to find daily bias.

There are many methods but you only need one clear approach that works for you.

In this document, you will learn 4 different tools to identify daily bias.

Your job is to study them, apply them, and discover which one aligns best with your trading style.

1

IRL & ERL

IRL is Internal Range Liquidity, and ERL is External Range Liquidity.

2

Daily Candle OHLC/OLHC

(Open Low-High Close / Open High-low Close)

3

M15 Orderflow

Short-term momentum confirms bias.

4

Previous Day High/Low

Historical levels act as support/resistance

IRL & ERL

IRL is Internal Range Liquidity, and ERL is External Range Liquidity.

WHAT IT IS

IRL is Internal Range Liquidity, and ERL is External Range Liquidity.

To simplify things we can look at **IRL as Fair Value Gaps** and **ERL as Highs and Lows**.

PRICE MOVEMENT

Most of the time, price moves from external liquidity to internal liquidity, and then from internal back to external, creating a continuous flow between the two.

External ↔ Internal

BIAS USE

To find daily bias using IRL & ERL, first identify the most recent IRL and ERL levels.

When price reaches one side (IRL or ERL), it often looks to move toward the opposite level. This movement helps you understand the likely directional expectation for the day.

Timeframes by Trader Type:

- Scalper: Focus on H1 and 15M for IRL & ERL levels. These levels give enough structure for short term trades.
- Day Trader: Focus on 4H and Daily for IRL & ERL levels. These levels help capture broader intraday expansions while aligning with the main daily trend.

CONFIRMATION

Once price reaches either the IRL or ERL level, wait for CISD
(Change in State of Delivery) to confirm the market's likely direction.
CISD acts as a confirmation signal before you consider taking a trade,

Timeframe Alignment for CISD Confirmation:

- Daily (1D) Level → Confirm on H1 CISD
- 4H Level → Confirm on M15 CISD
- H1 Level → Confirm on M5 CISD
- M15 Level → Confirm on M1 CISD

DAILY OHLC/OLHC

(Open Low-High Close / Open High-low Close)

WHAT IT IS

Every candle has four points:

- Open – where price starts for that time period
- High – the highest price reached
- Low – the lowest price reached
- Close – where price ends for that time period

If the **close is below the open**, that's a bearish candle.

If the **close is above the open**, that's a bullish candle.

OLHC (open - low - high - close)

OLHC means new candle opened, moved down first, then moved up, and closed higher, showing that sellers were active early but buyers finished stronger.

OHLC (open - high - low - close)

OHLC means price opened, moved up first, then moved down, and finally closed, showing that buyers were active early but sellers took control later.

BIAS USE

This method is designed mainly for day traders entering trades on M15 or M5 charts.

To find daily bias using the daily candle OHLC, your main focus should be on the previous day's range.

Previous day's range = Distance between the previous day's High and Low.

STEP 1

Analyze the previous day range

Mark the previous day's high and low.

Identify all previous day PD arrays (1D,4h,1H)

STEP 2

Wait for Price Interaction

Before the current daily candle opens, wait for price to reach key levels within the previous daily range.

Do nothing until price taps a marked PD array.

STEP 3

Identify Bias

After the daily candle opens, price may drop first and reach **previous day low** /a **bullish PD array** within the previous day's range.

That day's candle can then close as an **OLHC candle**, forming a possible bullish candle. This can indicate a **bullish bias for the day**.

After the daily candle opens, **price may rise first and reach previous day high / a bearish PD array** within the previous day's range.

That day's candle **can then close as an OLHC candle**, forming a possible bearish candle. This can indicate a **bearish bias for the day**.

STEP 4

Confirming Low / High

Finally, price reached the any of the previous day's level. **First, wait for the 1H CISD to confirm the low or high.** Once CISD is confirmed, you can take trades on lower timeframes.(m15/m5)

TIMING

Most daily candle expansions happen during the AM session.
For better accuracy in finding daily bias,
avoid trading during the Asian or London sessions.

Wait for the AM session to see how price reacts to the previous day's range.

2/4/2026
Wednesday

CHART EXAMPLE (NQ)

The previous day left a 4H SIBI inside its range. When the new day opened, price delivered straight into that imbalance, marking the daily candle high.

From that point, the market expanded heavily to the downside, driving with strong momentum, forming the daily low and eventually closing bearish.

On that day, if we look at the 1H chart, it's very clear. Price first reached the 4H SIBI, and then 1H CISD formed. This confirmed that the daily bias was bearish. After forming the 1H CISD, price retraced back into CISD and then dropped, following the bearish direction. This is why it's important to wait for the H1 CISD before taking trades it confirms the bias.

M15 ORDERFLOW

Short-term momentum confirms bias.

WHAT IT IS

Order flow is basically reading the market as it happens. It's about understanding who is controlling the price buyers or sellers at any given moment.

Instead of relying on complicated tools or indicators, order flow focuses on how price itself moves, because price reveals the actions of the "smart money" (institutions).

In practical terms:

- Watch how price reacts to key levels.
- Notice if price moves smoothly in one direction or struggles at certain levels.
- The movement of price tells you whether buyers or sellers are active, and where the market is likely headed next.

Order flow is like observing a river: you don't need to measure it with fancy instruments you just watch the current, direction, and flow. In trading, the "current" is price, and the "direction" shows the dominant force in the market.

By learning to read order flow, even beginners can align their trades with the larger market instead of guessing. It's the foundation of ICT trading because it focuses on real behavior, not predictions.

FLIP TOOL

Flip tools are the most important concept for understanding order flow. They help you identify which side of the market is in control and when that control changes. Instead of guessing the direction, flip tools confirm when buyers take control from sellers, or sellers take control from buyers. This confirmation tells you that order flow has changed.

There are two main flip tools:

1.Change in State of Delivery (CISD)

CISD happens when the market shifts from one direction to another. For example, if price was moving up (buyers in control) and suddenly starts closing strongly in the opposite direction, it signals that sellers may be taking control. This change confirms that the previous order flow is weakening and a new direction may begin.

2.Inversion

Inversion happens when a Fair Value Gap (FVG) fails and price closes on the opposite side of it. This failure shows that the previous imbalance is no longer respected, and control may be shifting to the other side of the market.

For example:

If there is a bullish Fair Value Gap and price comes back into it, but instead of respecting it and moving higher, price closes below the gap, that bullish FVG has failed. This failure confirms that sellers are gaining control. The bullish imbalance can now act as resistance, supporting a bearish move.

Bullish CISD : Price is moving down, then a down-close candle (or a series of them) gets closed above its opening price. This signals a potential move higher.

series of candle

one candle

Bearish CISD : Price is moving up, then an up close candle (or a series of them) gets closed below its opening price. This signals a potential move lower.

series of candle

one candle

Bullish inversion : A bearish Fair Value Gap that price fails to respect. When price closes above the bearish FVG, it becomes a Bullish Inverse Fair Value Gap.

Bearish inversion : A bullish Fair Value Gap that price fails to respect. When price closes below the bullish FVG, it becomes a Bearish Inverse Fair Value Gap.

BULLISH ORDER FLOW

Bullish order flow simply means the market is moving up because buyers are stronger than sellers.

4 characteristics to identify bullish order flow:

Bearish order flow

Bullish order flow

BEARISH ORDER FLOW

Bearish order flow simply means the market is moving down because sellers are stronger than buyers

4 characteristics to identify bearish order flow:

Bullish order flow

Bearish order flow

BIAS USE

This method works only when entries are taken on the 1-minute chart.

First, confirm the overall order flow on the 15-minute timeframe.
Next, wait for the 5-minute order flow to align in the same direction.
When both the M15 and M5 are aligned, your directional bias is confirmed.

Finally, drop to the 1-minute chart and wait for the M1 order flow to align with the M15 and M5. Only then should you execute your trade.

In simple terms:

M15 + M5 + M1 order flow must all be in the same direction before entering a trade.

M15 Bullish	M5 Bullish	M1 Bullish	Long trades
M15 bearish	M5 bearish	M1 bearish	Short trades
M15 bearish	M5 Bullish	M1 bearish	No trades
M15 Bullish	M5 bearish	M1 bearish	No trades

15 minute

First, wait for one-side order flow to be confirmed on the 15-minute chart.

Once order flow is confirmed:

If the order flow is bullish, focus on price retracing down into bullish PD arrays.

If the order flow is bearish, focus on price retracing up into bearish PD arrays.

This timeframe is used only to define directional bias, not for entries.

M15

5 minute

After the 15-minute order flow is confirmed, move to the 5-minute chart.

- Wait for the 5-minute order flow to align in the same direction as the 15-minute.
- No trades should be taken if the 5-minute order flow is not aligned with the 15-minute bias.

This step ensures internal structure confirmation.

M15

M5

1 minute

Once both the 15-minute and 5-minute order flow are aligned:

- Shift your focus to the 1-minute chart.
- Use any valid entry model (CISD, FVG, Breaker, Inversion, etc.)

This timeframe is used strictly for execution.

M1

TIMING

Use this method to find bias only between 9:30 AM and 11:30 AM (EST).
This method is not recommended outside this time window.

PD HIGHS & LOWS

Historical levels act as support/resistance

WHAT IT IS

Previous Day High (PDH) and Previous Day Low (PDL) are the highest and lowest prices reached during the prior trading day.

- PDH: Maximum price of the previous day
- PDL: Minimum price of the previous day

These levels are crucial because they act as natural liquidity pools, where stop losses, take profits, and pending orders are often placed.

Traders can use PDH and PDL to anticipate market moves, frame daily bias, and identify areas where price may reverse or continue.

BIAS USE

PDH and PDL help determine the market’s likely direction for the day:

Bullish Bias

Price respects PDL (does not close below)
Expect price to target the next PDH.

Price breaks and closes above PDH
Expect price to target the next PDH.

Bearish Bias

Price respects PDH (fails to close above)

Expect price to target the next PDL.

Price breaks and closes below PDL

Expect price to target the next PDH.

Neutral Bias

Price oscillates between PDH and PDL

Wait for a breakout or a failure to displace (FTD) to define bias

TFS FRAMEWORK

Simplifying ICT concepts for traders

What You'll Learn Inside the TFS Framework

- The TFS framework and its core logic
- The strengths and limits of the ICT concept
- Why most ICT traders struggle to stay consistent
- Why clarity matters more than more strategies
- How to build a simple, executable trading plan

You'll also understand:

- Internal & external liquidity
- How liquidity is targeted
- True order flow
- Market structure and price behavior
- PD arrays (premium & discount logic)
- The phases of price movement
- Proper timeframe alignment
- SMT and inter-market weakness

Finally, you'll get:

- The complete TFS trading model
- A repeatable process you can follow every day
- No indicators. No guesswork. No clutter.
- Just structure, clarity, and execution.

Built for traders who want simplicity, precision, and consistency
